

Combination Of Liposculpture With Chin Augmentation For Jaw Line Reshaping Dr. Kuang-Te Chen 陳廣得

Modern advances in rejuvenation of the aging face have minimized morbidity and recovery time and maximized natural aesthetic results. Liposuction with or without autologous fat transfer techniques have emerged as popular methods to achieve these ends. Used alone, or in conjunction with other modalities, lipocontouring will likely continue to play a prominent role in facial aesthetic and reconstructive surgery. For some specific patients presenting as a wide face associated with prominent buccal fat and short chin, liposuction alone can only reduce fat of cheek and further enhance the hypoplasia of the lower face. Chin augmentation alone usually results in a prominent non-smooth even a depressive contour at the chin-cheek junction. For those patients with a wide face associated with prominent cheek fat and short chin, combination of liposculpture at the cheek area with simultaneous chin augmentation can achieve the best results. Combination of facial liposculpture with chin augmentation can greatly change the facial profile from the wide and short face to a relatively narrow and not short facial profile with a short recovery time.
